

!. Body Weight (bwt) vs Litter Weight (hwt)

The points are spread out, but the regression line slops slightly upward. This suggests a weak positive relationship between lwt and bwt. In general, higher lwt values are associated with somewhat higher bwt values, but the larger amount of scatter shows that lwt does not explain bwt very strongly by itself. There are also a few points far from the main

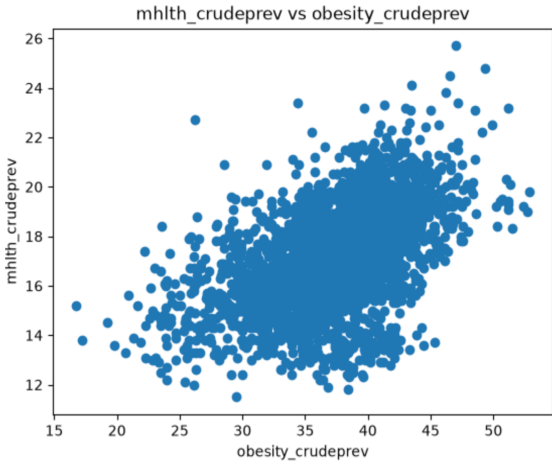

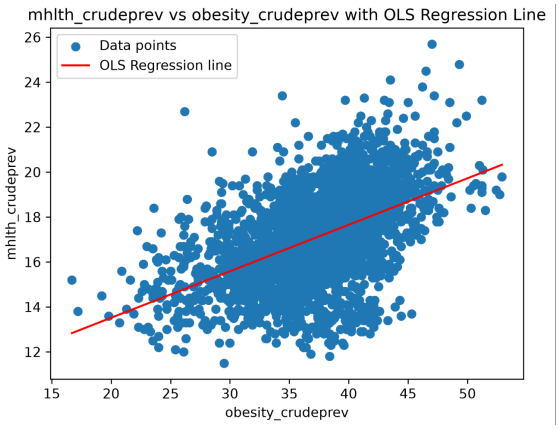

cluster.

2. Most of the observation are concentrated at the lower end of the total population, while housing insecurity prevalence varies widely. The OLS line slopes upward, which suggests a

small positive relationship between total population and housing insecurity prevalence. However, a few very large population observations are far from the main group and may have a strong effect on the fitted line.

3. These graphs shows a clearer positive pattern than the other two relationship. As obesity prevalence increases, poor mental health prevalence also tends to increase. The regression line has a noticeable upward slope, and many of the points follow the same general direction. There is still variation, so obesity prevalence does not perfectly predict poor mental health prevalence.

Conclusion:

All three regression lines slope upward. The obesity and poor mental graph show the clearest positive relationship, while the other two relationship are wreaker and more scattered.
